Report Summary

Why do some things catch on? Academics and popular press writers alike have long been interested in cultural dynamics, or why some songs, movies, and other cultural items become popular. Some songs become hits, for example, while others fail, and some movies become blockbusters while others don't. Why are some cultural items more successful than others? And how can managers use these insights to help make their products and services more popular?

In this study, Jonah Berger and Grant Packard suggest that how different cultural items are to others out there currently may help shape success. Research has demonstrated the important influence of culture on individual-level psychological processes; at the same time, these individual-level processes shape the norms, practices, and items that make up collective culture. In particular, people have a drive for stimulation and value items that are different from what they have experienced before. This suggests that cultural items that are more atypical, or differentiated from their peers, may be liked more and, consequently, become more popular.

The researchers use natural language processing of thousands of songs to examine the relationship between lyrical differentiation (i.e., atypicality) and song popularity. Using Billboard's digital download rankings (www.billboard.com/biz), they sampled ranking data once every three months over a three-year period (2014-16) for each of seven major genres (Christian, country, dance, pop, rap, rock, and R&B). They acquired the complete lyrics for each of these songs at SongLyrics.com and used latent Dirichlet allocation to determine the main themes discussed across songs.

They calculate differentiation (atypicality) as the absolute value difference between a song's lyrics and the genre mean, and aggregate these differences across topics. Finally, OLS regression examines the relationship between lyrical differentiation and song performance (i.e., chart ranking).

Results indicate that the more different a song's lyrics are from its genre, the more popular it becomes. A 16% increase in lyrical differentiation, for example, is associated with a one-position improvement in chart ranking. This relationship holds controlling for a range of factors including radio airplay, artist, time, the topics themselves, number of words, language complexity, and other major linguistic features. A partitioned regression model shows that this relationship is weaker in genres where lyrics matter less (i.e., dance) or where differentiation matters less (i.e., pop) and occurs for lyrical topics but not style.

Overall, the results shed light on cultural dynamics, why things become popular, and the psychological foundations of culture more broadly. They also suggest that managers making cultural products may want to highlight difference as a way to drive success.

Jonah Berger is Associate Professor of Marketing, Wharton School, University of Pennsylvania. Grant Packard is Assistant Professor, Marketing, Lazaridis School, Wilfrid Laurier University.

Acknowledgments

The authors thank Shawn Zamechek for assistance with the LDA analysis.

Why do some things catch on? Academics and popular press writers alike have long been interested in cultural dynamics, or why some songs, movies, and other cultural items become popular (Kashima 2014; Lieberman 2000; Simonton 1980). Some songs become hits, for example, while others fail, and some movies become blockbusters while others don't. Why are some cultural items more successful than others?

One possibility is that popularity is random. Even domain experts have difficulty predicting success (Bielby & Bielby, 1994), and researchers have argued that popularity is driven by chance patterns of social influence (Hahn & Bentley, 2003; Salganik, Dodds, & Watts, 2006). These perspectives suggest that success has little to do with features of the cultural item themselves.

Building on research on the psychological foundations of culture, however, we suggest that the similarity between related cultural items may help shape success. Research on cross-cultural psychology has demonstrated the important influence of culture on individual-level psychological process (Markus & Kitayama, 1991). But the reverse is also true; psychological processes shape the norms, practices, and items that make up collective culture (Norenzayan et al., 2006; Kashima, 2008; Schaller & Crandall, 2004). In particular, people have a drive for stimulation (Zuckerman, 1979), and from an early age, children are attracted to novel stimuli, or those that are different from what they have experienced before (Flavell, Miller, & Miller 2001). This suggests that context should shape cultural success. The other things people have experienced should determine how novel a given new cultural item seems. Taken to a collective level, cultural items that are more atypical, or differentiated from their peers, may be liked more, and, consequently, become more popular.

Unfortunately, empirically testing the link between differentiation and cultural success has been constrained by the ability to easily quantify differences between cultural items at scale. To address this issue, we use textual analysis to measure lyrical differentiation across thousands of songs, examining whether more lyrically differentiated songs are more successful. Importantly, the differentiation we examine is bounded, not infinite. A Country song whose lyrics sound like Death Metal would be quite different from most Country songs, but would also be unlikely to be classified as a Country song in the first place. Thus, we examine whether *among* songs classified as belonging to a given cultural category (i.e., genre; Lena & Peterson, 2008), those whose lyrics are more atypical, or differentiated from other category members, are more successful.

Method

First, we collected data on song popularity. To focus on individuals' preferences, we used Billboard's digital download rankings (www.billboard.com/biz) which capture over 90% of major paid song services (e.g., Apple iTunes and Google Play). We focused on this measure of popularity, rather than say, radio airplay, because it is more likely to be driven by individual preferences rather than a small number of institutionalized actors (e.g., DJs). We sampled the ranking data once every three months over a three-year period (2014-16) for each of seven major genres (Christian, Country, Dance, Pop, Rap, Rock and R&B). Comprehensive data was unavailable for the Alternative genre. We obtained all songs that appeared in each genre ranking and their position in that genre's chart (1-50). We reverse code song ranks so that positive coefficients describe a positive relationship with song success. This resulted in a dataset of 4,200 song rankings and 1,879 unique songs. We captured artist name and whether the song appeared on the Billboard radio airplay lists for the same periods as covariates.

Second, we acquired the complete lyrics for each of these songs at SongLyrics.com.

Third, we used latent Dirichlet allocation (LDA; Blei, 2012) to determine the main themes discussed across songs. This approach takes texts (e.g., song lyrics), and by measuring word co-occurrence within and across texts, determines the key latent topics or themes that make up those texts, and the words that make up each topic (Table 1; see Supplemental Materials for more detail on the methodological approach). Aggregating across all songs within a genre provides that genre's average topic composition (Figure 1). Country songs, for example, sing a lot about "girls and cars" (39%) and less about "body movement" (2%).

Table 1. Topics and Demonstrative Topic Words

<u>"Anger and Violence"</u> bad, dead, hate, kill, slay	<u>"Body Movement"</u> body, bounce, clap, jump, shake	<u>"Dance Moves"</u> bop, dab, mash, nae, twerk	<u>"Family"</u> american, boy, daddy, mamma, whoa	<u>"Fiery Love"</u> burn, feel, fire, heart, love
<u>"Girls and Cars"</u> car, drive, girl, kiss, road	<u>"Positivity"</u> feel, like, mmm, oh, yeah	<u>"Spiritual"</u> believe, grace, lord, one, soul	<u>"Street Cred"</u> ass, b*tch, dope, rich, street	<u>"Uncertain Love"</u> aint, cant, love, need, never

Note: Longer lists of high probability words by topic are presented in table S1.

Fig. 1. Relative Use of Lyrical Topics by Genre

Note: Values indicate the difference between a genre's topic use and the average topic use across all songs, where zero (grey dotted line) indicates no difference. Country songs, for example, sing 27% more about "girls and cars" than the average song. Panel **A** depicts genres with more extreme variation in topic use, Panel **B** depicts genres with less extreme variation in topic use.

Fourth, we calculate how lyrically different each song is from its genre. For each topic, we take the absolute value difference between that song's lyrical topic composition and the genre mean. Then, we aggregate these differences across topics using Ireland and Pennebaker's (2010) language style matching equation. We invert the resultant value to describe differentiation (rather than matching).

Finally, OLS regression examines the relationship between lyrical differentiation and song performance. Analysis treating rank dependent measures as continuous is appropriate given the large number and fixed range of ranks.

Results

Results indicate that the more differentiated a song's lyrics are from its genre, the more popular that song is ($B = 6.45$, $t = 3.23$, $p = .001$, Table 2, model 1, Figure 2). A 16% increase in lyrical differentiation, for example, is associated with a one-position improvement in chart ranking. Results are the same using an ordinal logistic specification (proportional odds; estimate = 0.77, $t = 3.22$, $p = .001$) or log transformation of the rank dependent measure ($B = 0.18$, $t = 3.42$, $p < .001$). Results are also the same using alternative methods of calculating lyrical differentiation, such as squared (rather than absolute value) differences ($B = 43.08$, $t = 2.83$, $p = .005$) and Jensen-Shannon divergence ($B = 155.14$, $t = 3.10$, $p = .002$).

Fig. 2. Impact of Lyrical Differentiation across Genres.

Note: Coefficient estimates and 95% confidence intervals for all songs (first row) and partitioned across genres (subsequent rows) for the main OLS regression. The effect is significant for a genre if the confidence interval does not intersect with zero. In some specifications, Pop has a significantly negative coefficient, suggesting that lyrical differentiation may sometimes *hurt* Pop music success.

Robustness Checks. We included numerous covariates in the model to assess the stability of the main result and rule out alternative explanations. Even controlling for a range of factors including radio airplay, artist, time, and the topics themselves, the effect of lyrical differentiation remains significant ($B = 8.01$, $t = 3.27$, $p = .001$, Table 2, model 2). We also considered other factors pertaining to lyrical content. One might wonder whether things like the number of words, language complexity, or other major linguistic features not captured by our LDA approach could explain the results. To account for these, we ran a model adding word count, six letter words (a proxy for language complexity or sophistication;), and baskets of words empirically linked to social or psychological constructs (cognitive processing, emotion, sociality, perception, motivation, time, relativity, and formality) from the Linguistic Inquiry and Word Count (LIWC) dictionaries (Pennebaker, Boyd, Jordan, & Blackburn, 2015). Even including these factors, however, and lyrical differentiation remained significant ($B = 8.38$, $t = 3.38$, $p < .001$, Table 2, model 3).

Finally, we considered whether individual words, rather than the bundles of words used in our LDA-based approach or the LIWC dictionaries might explain the results. Even after including dummies for the presence of each of the 100 most frequent words used across all songs, however, the effect for lyrical differentiation remained significant ($B = 8.08$, $t = 2.52$, $p = .01$, Table 2, model 4). In sum, across a variety of specifications, lyrical differentiated songs were more popular.

To best identify lyrical differentiation's effect, one would ideally keep all other song aspects the same, vary lyrical differentiation, and examine its influence on popularity. To approximate this, we examine songs that chart in two different genres at the same time. While artist, lyrics, and any other textual features of the song are identical (it is the same song), lyrical

differentiation will be greater in one genre than the other, providing a stricter test of lyrical differentiation's impact. If the same song by the same artist is more successful in the genre in which it is more lyrically differentiated (versus one in which it is less differentiated), this would support the notion that lyrical differentiation, rather than some other factor, is driving popularity.

To test this possibility, we analyze the 410 songs that appear on two different genre charts at the same time using an analysis approach similar to difference-in-differences. We calculate the lyrical differentiation of each song from each of its two genres and difference these values. Results underscore the prior findings, indicating that songs are more popular in genres where they are more lyrically differentiated ($B = 34.64$, $t = 3.00$, $p = .003$). This, combined with additional analyses (see Supplemental Materials), including finding the same result using a matched comparison group of less popular (i.e., non-ranked) songs by the same artist from the same album, a model accounting for right truncation, and a two-stage Heckman selection model all cast doubt on the notion that selection can explain the results.

Results also remain the same (see Supplementary Materials) controlling for topical diversity (entropy) and alternative approaches to calculating topics (e.g., within genre) or differentiation (i.e., across time).

Variation by Genre. While lyrically differentiated songs are more popular, might this relationship vary by genre? Lyrics may matter less in Dance music, for instance, where attributes that drive movement (e.g., the beat) may be more important than lyrics. Results are consistent with this prediction (Figure 2). A partitioned regression model shows that while lyrical differentiation is linked to popularity in most genres, the relationship is weaker in Dance, as well as Pop music, which, almost by definition, is more about mainstreaming than differentiation (Frith, 1986).

Type of Atypicality. Further analyses shed light on the type of differentiation linked to success. While Country songs with more differentiated lyrics are more successful, for example, is this because they include *more* Country-associated content (i.e., more “girls and cars” and other genre-typical lyrics than other Country songs) or because they include *less* Country-associated content?

Results indicate that successful songs use *less* genre-typical topics ($B_{\text{Typical topics}} = -3.60, t = 3.28, p = .001$). In terms of what takes their place, use of less typical topics like “uncertain love” ($t = 2.78, p = .005$) and “dance movement” ($t = 2.69, p = .007$) are generally linked to greater popularity. Less-used topics linked to success also sometimes vary by genre. For example, “street cred” represents only 2% of Rock lyrics, yet Rock songs that sing more about it are more popular ($B = -35.65, t = 2.30, p = .02$). Additional results are reported in Supplemental Materials.

Topical vs. Style Differentiation. While more topically differentiated songs are more popular, the same does not hold for stylistic differentiation. Linguistic topics (or content) refers to *what* someone is discussing (e.g., cars, love, or money), but linguistic style refers to the small subset of words (e.g., prepositions and conjunctions) that relate to *how* a person writes or speaks (Ireland & Pennebaker, 2010). Stylistic differentiation, however, does not predict success ($B = 0.11, t = 0.05, p = .96$; see Supplemental Materials). Further, the relationship between topical differentiation and popularity persists even controlling for stylistic differentiation ($B = 8.17, t = 2.28, p = .02$). This suggests that successful songs tend to sing about different topics, but not necessarily in a different style (though specific stylistic word features, on their own, may be linked to popularity).

Discussion

Though some have argued that cultural success is impossible to predict, textual analysis of thousands of songs suggest that those whose lyrics are more differentiated from their genres are more popular. This dovetails with recent perspectives on the psychological foundations of culture (Kashima, 2008; Schaller & Crandall, 2004). When shared across individuals, psychological processes can shape the practices and items that constitute culture. In this case, value for novelty or difference may underlie the link between lyrical differentiation and cultural success.

Might different aspects (e.g., music vs. lyrics, cinematography vs. script, or medium vs. content of art) play different roles in cultural adoption? In songs, for example, would melodic differentiation also be beneficial? While extrapolation from our findings might suggest yes, melodic elements may be particularly important in determining how people classify a song (e.g., banjo signals Country). If so, lyrics may be freer to deviate from genre norms.

Different aspects of cultural products (e.g., music and lyrics) may also combine to shape differentiation, and thus popularity. Though novelty can be good, there are also benefits to familiarity (Kunst-Wilson & Zajonc, 1980). Rather than achieving the right balance on just one dimension alone, successful cultural items may mix similarity and differentiation across dimensions. Similar enough to expectations to evoke the warm glow of familiarity but differentiated enough to feel new and exciting. Many remixes, for example, add new lyrics to an old tune or vice versa. Differentiation on one dimension may be balanced by similarity on the other.

Finally, our findings highlight the value of natural language processing to study cultural dynamics. From digitized books and social media posts, to news coverage and the congressional

record, more and more texts have become available that can facilitate the study of culture (Mehl, Vazire, Ramírez-Esparza, Slatcher, & Pennebaker, 2007; Pennebaker, Mehl, Neiderhoffer, 2003). Further, advances in natural language processing and computational social science provide a rich set of opportunities to extract cultural and behavioral insight from text. Hopefully, this emerging toolkit will help provide deeper insight into why things catch on.

Author Contributions

All authors contributed to the study design and data collection. G. Packard performed the data analysis and interpretation with help from J. Berger. J. Berger drafted the manuscript and G. Packard provided critical revisions. All authors approved the final version of the manuscript for submission.

SUPPLEMENTAL ONLINE MATERIALS

Additional Details Regarding Topic Modeling

We used latent Dirichlet allocation (LDA) to determine the main themes discussed across songs. LDA takes a number of texts (e.g., songs), and by measuring word co-occurrence within and across texts, determines the key latent topics or themes that make up those texts, and the words that make up each topic. Each word has a probability of appearing in each topic, with words that are more relevant to a given topic having higher probability.

We pre-processed the data using common techniques (Hopkins & King 2010) including removing punctuation, numbers, and stemming related words (e.g., forest, forests and forested all appear as “forest”). Results were robust to the inclusion/exclusion of both infrequent words and stop words (Lewis, Yang, Rose, & Li, 2004). Both were included in the final analysis given that common stop words (e.g., personal pronouns like “I” and “you”) occurred frequently in the data and offer interpretive value (e.g. self- vs. other-involvement; Tausczik & Pennebaker, 2010). All LDA models used Gibbs sampling at 5,000 iterations with a random seed starting point.

We followed prior research (DiMaggio, Nag, & Blei, 2013; Hansen, McMahon, & Prat, 2014) in determining the number of topics. The number of topics (K) to use generally depends on a combination of predictive model fit and face validity or interpretability of topics that emerge at different K. Research incorporating semantic interpretation of topic models frequently settle on a range of seven to 13 topics given diminishing interpretive value of topics after this point with minimal loss in predictive model fit for the focal relationship (DiMaggio, Nag, & Blei, 2013; Chang, Boyd-Graber, Gerrish, Wang, & Blei, 2009).

We performed LDA analysis at levels of K from five to 15, and chose the number that maximized statistical reliability, interpretability, and parsimony. Our main results are robust to a

wide range of values of K . The relationship between lyrical differentiation and song popularity is significant at 99% confidence or better at K greater than six. Goodness of fit statistics suggest little benefit as K increases (adjusted R-squared range = 0.10 - 0.11 and conditional R-squared range [Nakagawa & Schielzeth, 2013] = 0.30 - 0.31 for K from seven to 15). We observed modest peaks in model fit at 10 topics. Researcher interpretation of the topics and predictive fit for individual topics also suggested diminishing benefit of reporting more than 10 topics. Thus, in the main text we report results at $K = 10$. While the perplexity fit measure for topic models reveals a stable improvement in fit (lower perplexity) as K increases, this statistic holds little relationship with interpretability or predictive model fit (Chang, Boyd-Graber, Gerrish, Wang, & Blei, 2009) and so was not used in selecting K .

Representative high probability words for each of the ten topics appear with interpretative labels for these topics in table S1. The topic with words like “car,” “drive,” and “girl,” for example, may be labeled as “girls and cars” and the topic with words like “shake,” “bounce,” and “clap” can be labeled as “body movement.” We use these latent topics to calculate each genre’s average lyric topic composition.

The LDA model outputs the proportion of each song that belongs to each latent topic. A given song, for example, might be 25% “girls and cars,” 10% “body movement,” and so on, with the 10 topics summing to 100%. Averaging each topic’s proportion across all songs in a genre provides that genre’s mean topic composition. Figure 2 (in the main text) depicts the prevalence of each topic in each genre relative to the mean incidence of these topics across all songs (i.e., the 0 point). Christian songs are more likely to sing about “spiritual” topics (words like believe, soul, and will), for example, while Rock songs are more likely to contain lyrics about “fiery love” (words like burn, heart and fire).

Robustness Checks

First, one could argue that rather than being driven by consumer demand, the results are driven by promotional activity, or in this case, radio airplay. Differentiated songs may be played more on the radio, and that repeated exposure, rather than lyrical differentiation itself, is what drives success. To test this possibility, we measured promotional activity by capturing whether a song appeared on Billboard's radio airplay charts the week prior to when it appeared on the download list (*Radio airplay*; $M = 0.21$, $SD = 0.40$).

Second, we included random effects for artist. Songs by more popular artists may get more attention (Adler, 1988; Rosen, 1981), for example, and if popular artists happen to use more differentiated lyrics (or unpopular artists tend to use less differentiated lyrics) one could argue this is driving the observed relationship between lyrics and success.

Third, because a variety of unobserved song-level factors such as producer or instrumentation could differentially impact song popularity, we nest a random effect for song within the artist effect.

Fourth, rather than a song's differentiation from other genre songs in how much it sings about "uncertain love," for example, it could be that what matters is just how much "uncertain love" a song sings about. We incorporate fixed effects for each of the 10 topics to account for this possibility.

Fifth, we control for the number of genres with which a song was associated (*Multi-genre count*; $M = 1.32$, $SD = 0.48$). Multi-genre songs may differentially benefit from broader market presence or, alternatively, experience muted effects of lyrical differentiation given their genre-bending status because the genre norms against which the song may deviate are less defined.

Sixth, we account for time by including fixed effects for each of the 12 quarterly song success measures. There may be time-specific factors driving song success such as seasonality or historical events. This factor also accounts for the fact that songs released in early chart periods have more opportunity to be ranked over multiple periods than songs released later in time.

Seventh, we control for a song's prior success by measuring the number of times the song had appeared among the top 50 songs in prior quarters (*Times charted*; $M = 4.04$, $SD = 3.55$).

Our focal effect of lyrical differentiation remains significant after including all of these factors in the model ($B = 8.01$, $t = 3.27$, $p = .001$; Table 2, model 2).

Addressing Selection Bias. While our results demonstrate that more popular songs have more differentiated lyrics, one could argue that the relationship is driven by the particular sample used (i.e., selection). Maybe highly popular songs have more differentiated lyrics than somewhat popular songs, for example, but relatively unpopular songs are also less differentiated.

We tried to address this with the breadth of data analyzed (i.e., thousands of songs across multiple years and a range of genres), but we also address it four additional ways. First, we collected an alternative sample of less popular songs. The number of unpopular songs is effectively unbounded, making random sampling challenging, so we created a matched comparison group of less popular songs by the same artists. For three of our ranking periods (i.e., 1,050 ranked songs), we took each artist with a song on the chart in that period and randomly selected another song from that artists' album that did not make the top 50 in any period.¹ We then recalculated genre topic means and lyrical differentiation for all songs including these additional less popular songs. This comparison allows us to test whether among

¹ In a small minority of cases, the top 50 song had been released as a single or on a compilation album of varied artists. In these cases, we selected either the most recent prior single or a random song from the most recent prior album by the top 50 song artist. Effects sustained after including dummy variables controlling for these songs.

songs by the *same* artists, released at the *same* time, appearing on the *same* albums, those that achieve greater popularity have more differentiated lyrics. Even using this stricter within-artist comparison, the relationship between differentiation and popularity persists. Compared to less popular songs by the same artist, more popular (i.e., top 50) songs were more lyrically differentiated from their genres ($M = .25$ vs. $M = .27$; $B = 0.02$, $t = 6.24$, $p < .001$). Using the main model and treating less popular songs as rank 51 shows the same result ($B = 29.59$, $t = 6.14$, $p < .001$).

Second, results persist accounting for right truncation in the song rank dependent measure (truncated Gaussian, Heckman, 1976; $B = 14.41$, $t = 30.07$, $p < .001$).

Third, we ran a two-stage Heckman selection model (Heckman, 1979) using the matched set of more and less popular songs from the within-artist analysis. Consistent with those results, the first stage probit model confirms that increased lyrical differentiation indeed predicts membership in the top 50 ($B = 2.32$, $t = 6.16$, $p < .001$). Importantly, however, a non-significant inverse Mills ratio ($\lambda = -106.93$, $t = 0.6$, $p = .55$) in the second stage (outcome) model indicates that selection does not affect the relationship between lyrical differentiation and song performance.

Fourth, as reported in the main text, we find the same result using songs that simultaneously charted in multiple genres.

Lyrical Topic Diversity. One might wonder whether rather than lyrical differentiation, the results are driven by entropy. Songs that are more differentiated may also sing about more topics, which may add richness or nuance. To test this possibility, we used the two most common measures of entropy (Zhang & Grabchak, 2016). Although greater topical diversity is weakly linked to popularity (Shannon entropy $B = 4.32$, $t = 2.24$, $p = .03$; Renyi entropy $\alpha = 2$, $B = 2.93$,

$t = 1.94, p = .05$), lyrical differentiation remained significant when including either form of entropy in the model ($B_s > 12.32, t_s > 2.93, p_s < .001$).

Lyrical Differentiation by Genre and Time. Results are also the same when we calculate topics separately by genre. We performed the same LDA analysis (i.e., 10 topics) within each genre and then calculated lyrical differentiation. As in the main model, songs that were more lyrically differentiated from their genre were more successful ($B = 10.11, t = 4.01, p < .001$).

Results are also the same when we calculate lyrical differentiation for each song compared to the smaller set of peer songs that were ranked in the same genre at the same time ($B = 6.38, t = 3.14, p = .002$).

Ancillary Analyses

We conducted several ancillary analyses to provide additional insight into the nature of the observed effects.

More or Less Typical? To examine whether popular songs include more or less genre typical content, we isolated topics that were more or less typical for each genre. Topics were ranked based on the extent to which their proportional use within a genre deviated from the mean use of that topic across genres. We then calculated directional (rather than absolute) lyrical differentiation, aggregated separately across the five most typical topics and five least typical topics for each genre. We included these two variables as simultaneous predictors in the base specification.

As reported in the main text, results indicate that popular songs use *less* of the genre's typical topics ($B_{\text{typical topics}} = -3.60, t = 3.28, p = .001$). Breaking topics down further into typicality quintiles produces similar results, indicating that more popular songs use *less* use of

the top two (most genre typical) lyric topic quintiles (1st quintile $B = -1.86$, $t = 2.57$, $p = .01$; 2nd quintile $B = -1.56$, $t = 2.84$, $p = .005$).

These results suggest that popular songs tend to avoid genre-typical topics, but is there any pattern as to which less typical topics take their place? Songs that include more language from a genre's least typical topic are less popular (5th quintile $B = -1.16$, $t = 2.19$, $p = .03$), but given there is no aggregate relationship between popularity and slightly less typical topics (i.e., 3rd and 4th quintile $ts < 0.5$, $ps > .8$), we turn to individual topic differentiation to shed some light on this question.

Topic-Specific Differentiation? We explored whether individual topics may be more or less important in achieving lyrical differentiation both across and within genres. Regression models including the 10 topics as simultaneous predictors of song popularity suggest that less use of the topics labeled “street cred” and “anger and violence” ($ts > 1.84$, $ps < .05$) and more use of the topics labeled “uncertain love” ($t = 2.78$, $p = .005$) and “dance movement” ($t = 2.69$, $p = .007$) are linked to greater popularity.

Exploratory genre analyses suggest that while “street cred” is negatively related to popularity overall, it may be underutilized in Rock music. This topic represents only 2% of Rock lyrics, yet Rock songs that sing more about it are more popular ($B = -35.65$, $t = 2.30$, $p = .02$). Rock songs may also benefit from singing less about “girls and cars” ($B = 13.37$, $t = 2.47$, $p = .01$), and more about “family” ($B = -16.94$, $t = 2.69$, $p < .01$). Overall, the less-used topics linked to success seem to vary by genre.

Content vs. Style Differentiation. While linguistic content refers to *what* someone is discussing (e.g., cars, love, or money), linguistic style (Ireland and Pennebaker, 2010) refers to the use of a small subset of words (e.g., prepositions and conjunctions) that relate to *how* a

person writes or speaks. To test the relationship between stylistic differentiation and popularity, we followed the procedure outlined in Ireland and Pennebaker (2010) to calculate language style matching, transposing the final value to represent differentiation rather than matching. As discussed in the main text, results indicate that stylistic differentiation alone does not predict success ($B = 0.11$, $t = 0.05$, $p = .96$). Further, the relationship between content differentiation and popularity persists even controlling for stylistic differentiation ($B = 8.17$, $t = 2.28$, $p = .02$). This suggests that successful songs tend to sing about different topics or content, but not necessarily in a different style.

Non-Linear Effects of Differentiation. One might wonder whether the relationship between lyrical differentiation and popularity is non-linear. When squared or cubed terms were incorporated in the main model, however, they were not significant ($ts < 1$, $ps > .3$), though our main linear effect still persists. This suggests that the relationship between lyrical differentiation and popularity is linear rather than curvilinear.

Differentiation from Music More Generally. When studying cultural success, it's important to consider the exposure set. Most people primarily listen to specific genres, and lyrics that feel novel to a Country listener may not feel novel to someone who usually listens to Rap. When measuring aspects like similarity or differentiation, considering its effect across all music (rather than specific genres) may overstate people's actual exposure to music.

Indeed, when we measure differentiation from the entire set of songs across all genres, we find similar, albeit weaker results ($B = 4$, $t = 1.66$, $p = .10$) than the genre-specific differentiation we use in our analyses. How different a song is from its genre should be a better proxy of whether listeners will like it than how different that song is from all music.
